

Chapter 3: Bayesian Machine Learning

Maschinelles Lernen 1 -
Grundverfahren WS21/22

Prof. Gerhard Neumann
KIT, Institut für Anthropomatik und Robotik

Learning Outcomes

What will we learn today?

- Understand the “Bayesian formulation” of machine learning
- What are the 2 basics steps needed for Bayesian learning
- What are the advantages of being “Bayesian”?
- For which representations can Bayesian learning be done in closed form?
- How to compute the posterior and predictive distribution for Bayesian Linear Regression?
- How to compute the posterior and predictive distribution for Gaussian Processes?

Today's Agenda!

Bayesian Learning:

- Posterior and Predictive Distribution
- Bayesian estimation for Gaussians
- Maximum A-posteriori (MAP) Estimates

Bayesian Regression Algorithms:

- Bayesian Linear Regression
- Gaussian Processes

Basics:

Gaussian Identities:

- Completing the Square
- Gaussian Bayes Rules
- Gaussian Propagation

Bayesian Learning

So far:

- We mainly considered single models, i.e., a point estimate θ^* for the parameter vector

However, ...

1. As the data is noisy, the estimated **optimal parameter vector θ^* is also uncertain**
 - I.e. parameters are just random variables
 - We so far do not really know how wrong / uncertain our estimate θ^* is
2. We have also seen that **multiple models (ensembles, see trees + forests)** usually work better!

Motivation of Bayesian Learning:

- Estimate uncertainty in θ^*
- Find a **more robust** predictor by **averaging over** many predictors
- ... where each predictor is weighted by the probability of being “right”
- Use this estimate **to quantify uncertainty of the prediction**

1-step: Compute Posterior

Compute the probability of “being right” for a parameter θ using **Bayes theorem**:

$$\underbrace{p(\theta|\mathcal{D})}_{\text{posterior}} = \frac{\overbrace{p(\mathcal{D}|\theta)}^{\text{data likelihood}} \overbrace{p(\theta)}^{\text{prior}}}{\underbrace{p(\mathcal{D})}_{\text{evidence}}}$$

- **Prior**: Can encode our subjective belief
- **Posterior**: Probability of parameter vector given the data
- **Likelihood**: Specified by our parametric model \mathcal{D}
- **Evidence**: Normalization, can be used for model comparison (later)

2-step: Compute predictive distribution

Predicting of a new data-point x^* :

$$\underbrace{p(\mathbf{y}^* | \mathbf{x}^*, \mathcal{D})}_{\text{marginal likelihood}} = \int \underbrace{p(\mathbf{y}^* | \mathbf{x}^*, \boldsymbol{\theta})}_{\text{likelihood}} \underbrace{p(\boldsymbol{\theta} | \mathcal{D})}_{\text{posterior}} d\boldsymbol{\theta}$$

- Parameter vector $\boldsymbol{\theta}$ is integrated out
- Likelihood $p(\mathbf{y}^* | \mathbf{x}^*, \mathcal{D})$ is now purely determined by the data \mathcal{D}
- $p(\mathbf{y}^* | \mathbf{x}^*, \mathcal{D})$ is often called **marginal likelihood** as $\boldsymbol{\theta}$ is marginalized out

Intuition: If you assign each parameter estimator a “probability of being right”, the average of these parameter estimators will be better than the single one

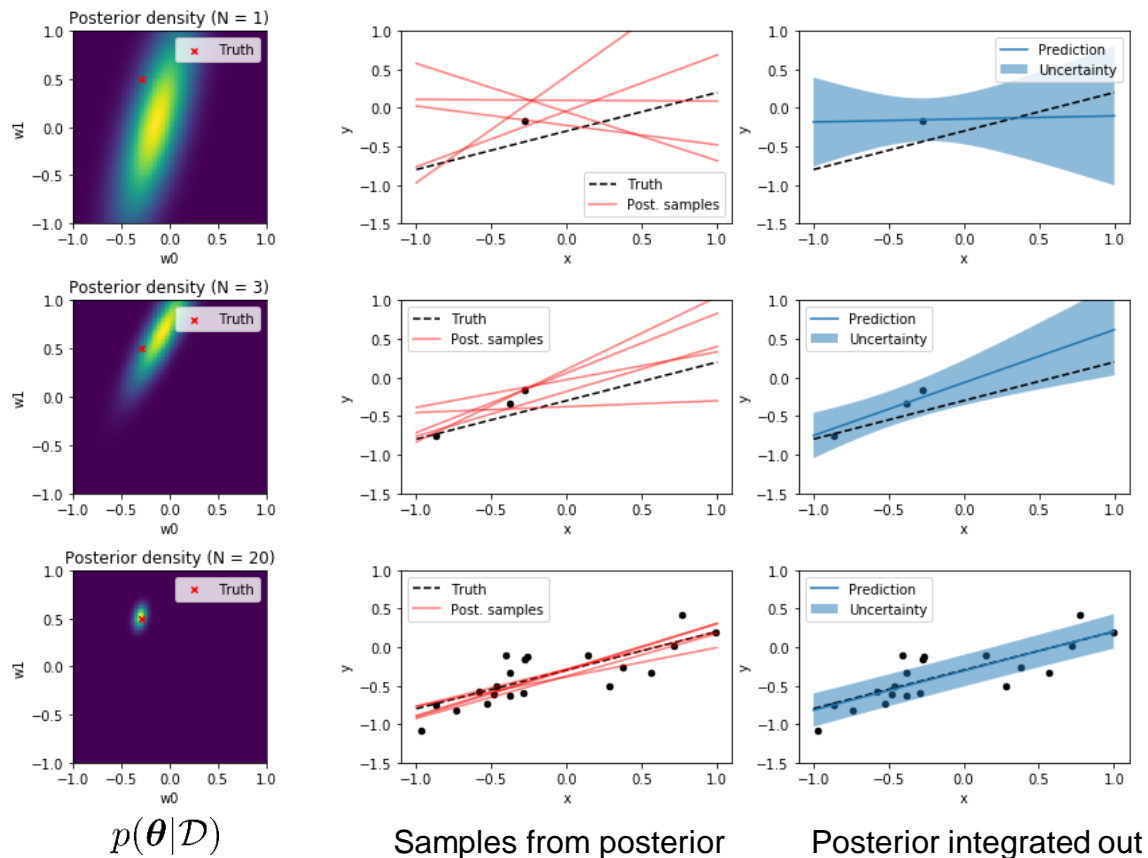

- Weighted ensemble method (with potentially infinite amount of models if integral can be solved exactly)
- ... often, samples from $p(\boldsymbol{\theta} | \mathcal{D})$ are used to approximate the integral (finite number of models in this case)

Example:

Bayesian Linear Regression (math comes later...)

Observation:

- The posterior becomes more narrow with more data

Priors

Prior $p(\boldsymbol{\theta})$ should capture our **belief and domain knowledge** as well as possible

What is our domain knowledge for a general ML algorithm?

- For most ML algorithms, we know that the weights $\boldsymbol{\theta}$ should be small
- This knowledge can be expressed with a **Gaussian prior, e.g.**

$$p(\boldsymbol{\theta}) = \mathcal{N}(\boldsymbol{\theta} | \mathbf{0}, \lambda^{-1} \mathbf{I})$$

- Most common for weight vectors (linear regression, neural nets...)
- λ is the precision of the prior
- However, many other priors are possible

Example: Gaussian Distribution

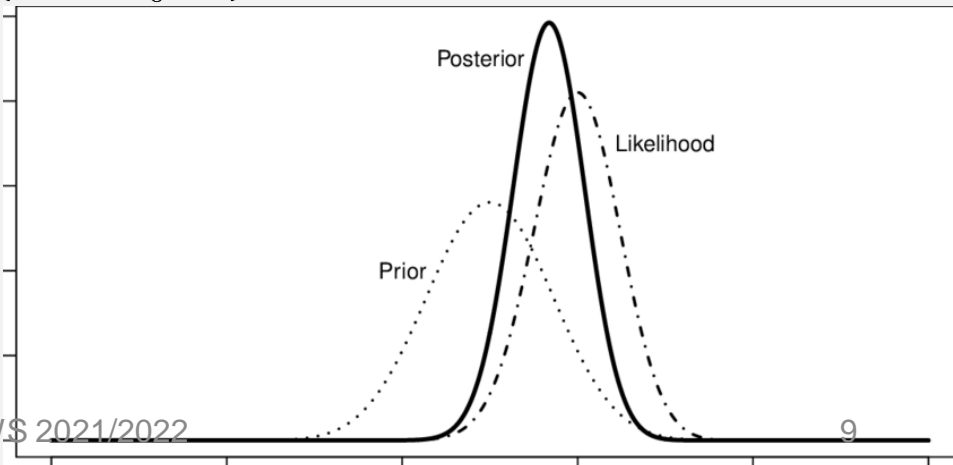

Likelihood (sample): $p(x|\boldsymbol{\theta} = \{\mu, \sigma\}) = \mathcal{N}(x|\mu, \sigma) = \frac{1}{\sqrt{2\pi\sigma^2}} \exp\left\{-\frac{(x - \mu)^2}{2\sigma^2}\right\}$

Likelihood (dataset): $p(\mathbf{X}|\mu, \sigma) = \prod_i p(x_i|\mu, \sigma) = \frac{1}{(2\pi\sigma^2)^{N/2}} \exp\left\{-\frac{\sum_i (x_i - \mu)^2}{2\sigma^2}\right\}$

Prior: $p(\mu) = \mathcal{N}(\mu|\mu_0, \sigma_0) = \frac{1}{\sqrt{2\pi\sigma_0^2}} \exp\left\{-\frac{(\mu - \mu_0)^2}{2\sigma_0^2}\right\}$

**Compute posterior $p(\mu|\mathbf{X})$ for μ
assuming σ is known:**

$$p(\mu|\mathbf{X}) = \frac{p(\mathbf{X}|\mu)p(\mu)}{p(\mathbf{X})}$$
$$\propto p(\mathbf{X}|\mu)p(\mu)$$

Basics: Completing the square

Posterior: $p(\mu|\mathbf{X}) \propto p(\mathbf{X}|\mu)p(\mu) \propto \exp \left\{ -\frac{\sum_i (x_i - \mu)^2}{2\sigma^2} - \frac{(\mu - \mu_0)^2}{2\sigma_0^2} \right\}$

Completing the square: Bring exponent in canonical squared form, i.e.

$$\exp \left(- \underbrace{\frac{1}{2}a\mu^2}_{\text{squared term}} + \underbrace{b\mu}_{\text{linear term}} + \text{const} \right)$$

Then we know that $p(\mu|\mathbf{X}) = \mathcal{N}(\mu|\mu_N, \sigma_N^2)$ with:

- Mean: $\mu_N = a^{-1}b$
- Variance: $\sigma_N^2 = a^{-1}$

Basics: Completing the square

Posterior: $p(\mu|\mathbf{X}) \propto p(\mathbf{X}|\mu)p(\mu) \propto \exp \left\{ -\frac{\sum_i (x_i - \mu)^2}{2\sigma^2} - \frac{(\mu - \mu_0)^2}{2\sigma_0^2} \right\}$

$$= \exp \left\{ -\frac{1}{2} \underbrace{\left(\frac{N}{\sigma^2} + \frac{1}{\sigma_0^2} \right)}_a \mu^2 + \underbrace{\left(\frac{\sum_i x_i}{\sigma^2} + \frac{\mu_0}{\sigma_0^2} \right)}_b \mu + \text{const} \right\}$$

Completing the square: $p(\mu|\mathbf{X}) = \mathcal{N}(\mu|\mu_N, \sigma_N^2)$

- Mean:
$$\mu_N = a^{-1}b = \frac{\sigma_0^2}{N\sigma_0^2 + \sigma^2} \sum_i x_i + \frac{\sigma^2}{N\sigma_0^2 + \sigma^2} \mu_0$$
$$= \frac{N\sigma_0^2}{N\sigma_0^2 + \sigma^2} \mu_{\text{ML}} + \frac{\sigma^2}{N\sigma_0^2 + \sigma^2} \mu_0$$
- Variance:
$$\sigma_N^2 = a^{-1} = \frac{\sigma^2 \sigma_0^2}{N\sigma_0^2 + \sigma^2}$$

Example: Posterior Distribution

The posterior is Gaussian with:

- Mean:
$$\mu_N = \frac{N\sigma_0^2}{N\sigma_0^2 + \sigma^2}\mu_{\text{ML}} + \frac{\sigma^2}{N\sigma_0^2 + \sigma^2}\mu_0$$
- Variance:
$$\sigma_N^2 = \frac{\sigma^2\sigma_0^2}{N\sigma_0^2 + \sigma^2}$$

Observations:

- Variance decreases with more training samples
- Will eventually reach 0
- Posterior mean interpolates between prior mean and sample average

Example: Computing the predictive distribution

The **predictive distribution** is given by:

$$\begin{aligned} \underbrace{p(x^*|\mathbf{X})}_{\text{marginal likelihood}} &= \int \underbrace{p(x^*|\mu)}_{\text{likelihood}} \underbrace{p(\mu|\mathbf{X})}_{\text{posterior}} d\mu \\ &= \int \mathcal{N}(x^*|\mu, \sigma) \mathcal{N}(\mu|\mu_N, \sigma_N) d\mu \dots \text{Gaussian propagation (proof not shown)} \\ &= \mathcal{N}(x^*|\mu_{x^*}, \sigma_{x^*}^2) \end{aligned}$$

The predictive distribution is **Gaussian** with:

- Mean: $\mu_{x^*} = \mu_N$
- Variance: $\sigma_{x^*}^2 = \sigma_N^2 + \sigma^2$

Observations:

- The predictive mean is the same as the posterior mean
- However, the predictive variance also considers the uncertainty of the mean

Conjugate priors

If the posterior distribution $p(\boldsymbol{\theta}|\mathcal{D})$ is in the **same probability distribution family** as the prior probability distribution $p(\boldsymbol{\theta})$, the prior and posterior are then called conjugate distributions, and **the prior is called a conjugate prior for the likelihood function**.

- In our example, the prior and posterior are Gaussian
- I.e. the **Gaussian distribution is conjugate** to itself

Other conjugate prior distributions:

- Gamma distribution is conjugate for the variance of a scalar Gaussian
 - Wishart distribution is conjugate for the covariance of a multivariate Gaussian
- ... won't be covered in the lecture but good to know it exists.

Summary: Bayesian Learning

1. Compute posterior:
$$\underbrace{p(\boldsymbol{\theta}|\mathcal{D})}_{\text{posterior}} = \frac{\overbrace{p(\mathcal{D}|\boldsymbol{\theta})}^{\text{data likelihood}} \overbrace{p(\boldsymbol{\theta})}^{\text{prior}}}{\underbrace{p(\mathcal{D})}_{\text{evidence}}}$$
2. Integrate out posterior:
$$\underbrace{p(\mathbf{x}^*|\mathcal{D})}_{\text{marginal likelihood}} = \int \underbrace{p(\mathbf{x}^*|\boldsymbol{\theta})}_{\text{likelihood}} \underbrace{p(\boldsymbol{\theta}|\mathcal{D})}_{\text{posterior}} d\boldsymbol{\theta}$$

Properties:

- For very large datasets, **the posterior will be a point estimate** $\lim_{n \rightarrow \infty} p(\boldsymbol{\theta}|\mathcal{D}_n) = \delta(\boldsymbol{\theta} - \boldsymbol{\theta}^*)$
 - I.e., Bayesian Learning will be equivalent to maximum likelihood
- **However, large advantage for smaller datasets!**
 1. We know where our **model is uncertain**
 2. More **robust estimate** due to averaging

Summary: Bayesian Learning

1. Compute posterior:
$$\underbrace{p(\boldsymbol{\theta}|\mathcal{D})}_{\text{posterior}} = \frac{\overbrace{p(\mathcal{D}|\boldsymbol{\theta})}^{\text{data likelihood}} \overbrace{p(\boldsymbol{\theta})}^{\text{prior}}}{\underbrace{p(\mathcal{D})}_{\text{evidence}}}$$
2. Integrate out posterior:
$$\underbrace{p(\mathbf{x}^*|\mathcal{D})}_{\text{marginal likelihood}} = \int \underbrace{p(\mathbf{x}^*|\boldsymbol{\theta})}_{\text{likelihood}} \underbrace{p(\boldsymbol{\theta}|\mathcal{D})}_{\text{posterior}} d\boldsymbol{\theta}$$

In most cases, both operations can not be performed analytically

- **Exception:** Bayesian Linear Regression + Gaussian Processes
- Very high-dimensional integrals, hard to compute
- **Simplification:** Maximum A-posteriori (MAP) Solution
- **Various Approximations:** Laplace Approximation, Variational Inference, Sampling, etc... (not covered)

Maximum a-posteriori solution

Simplification of Bayesian Learning:

1. Find the parameter vector θ_{MAP} that maximizes the posterior

$$\theta_{\text{MAP}} = \arg \max_{\theta} p(\theta | \mathcal{D}) = \arg \max_{\theta} p(\mathcal{D} | \theta) p(\theta)$$

- Uncertainty in θ is ignored
- Optimization is done in log-domain

$$\theta_{\text{MAP}} = \arg \max_{\theta} \log p(\mathcal{D} | \theta) + \log p(\theta)$$

2. Use θ_{MAP} for prediction

$$p(\mathbf{x}^* | \mathcal{D}) \approx p(\mathbf{x}^* | \theta_{\text{MAP}})$$

Maximum a-posteriori solution

MAP solution: $\boldsymbol{\theta}_{\text{MAP}} = \arg \max_{\boldsymbol{\theta}} (\log p(\mathcal{D}|\boldsymbol{\theta}) + \log p(\boldsymbol{\theta}))$

- Prior has similar role than **a regularization loss**

Example: Regression

- Gaussian likelihood $p(\mathcal{D}|\boldsymbol{\theta}) = p(\mathbf{Y}|\mathbf{X}, \boldsymbol{\theta}) = \prod_i \mathcal{N}(y_i|f_{\boldsymbol{\theta}}(\mathbf{x}_i), \sigma^2)$
- Gaussian prior $p(\boldsymbol{\theta}) = \mathcal{N}(\boldsymbol{\theta}|\mathbf{0}, \lambda^{-1}\mathbf{I})$
- Corresponding objective: $\arg \max_{\boldsymbol{\theta}} \underbrace{\sum_i -\frac{1}{2\sigma^2}(y_i - f_{\boldsymbol{\theta}}(\mathbf{x}_i))^2}_{\text{Sum of squared errors}} - \underbrace{\frac{\lambda}{2}\boldsymbol{\theta}^T\boldsymbol{\theta}}_{-\lambda/2\|\boldsymbol{\theta}\|^2} + \underbrace{c(\sigma^2, \lambda)}_{\text{only interested in } \boldsymbol{\theta}}$
 - Gaussian prior **corresponds to a L2 regularization** loss!
 - Gaussian likelihood **corresponds to squared** loss!

Example: MAP for Linear Regression

Remember: In linear regression $f_{\mathbf{w}}(\mathbf{x}) = \mathbf{w}^T \phi(\mathbf{x})$

Objective:

$$\mathbf{w}_{\text{MAP}} = \arg \max_{\mathbf{w}} \underbrace{\sum_i -\frac{1}{2\sigma^2} (y_i - \mathbf{w}^T \phi(\mathbf{x}_i))^2}_{\text{Sum of squared errors}} - \underbrace{\frac{\lambda}{2} \mathbf{w}^T \mathbf{w}}_{-\lambda/2 \|\boldsymbol{\theta}\|} + \underbrace{c(\sigma^2, \lambda)}_{\text{only interested in } \mathbf{w}}$$
$$= \arg \min_{\mathbf{w}} \sum_i (y_i - \mathbf{w}^T \phi(\mathbf{x}_i))^2 + \lambda \sigma^2 \mathbf{w}^T \mathbf{w} + c(\sigma^2, \lambda)$$

- The **MAP objective** for Linear Regression is equivalent to **Ridge Regression!**
 - with $\lambda_{\text{ridge}} = \lambda \sigma^2$

Example: MAP for Linear Regression

Objective:
$$\mathbf{w}_{\text{MAP}} = \arg \min_{\mathbf{w}} \sum_i (y_i - \mathbf{w}^T \phi(\mathbf{x}_i))^2 + \lambda \sigma^2 \mathbf{w}^T \mathbf{w}$$

Result:
$$\mathbf{w}_{\text{MAP}} = (\Phi^T \Phi + \lambda \sigma^2 \mathbf{I})^{-1} \Phi^T \mathbf{y}$$

- We have now 2 parameters:
 - λ ... sets the importance of the prior
 - σ^2 ... uncertainty of the training data
- } Can be set by optimizing log likelihood + log prior via cross validation
Q: Why do we need cross validation here?

Predictive Model:

$$p(y^* | \mathbf{x}^*, \mathcal{D}) \approx p(y^* | \mathbf{x}^*, \mathbf{w}_{\text{MAP}}) = \mathcal{N}(y^* | \mathbf{w}_{\text{MAP}}^T \phi(\mathbf{x}^*), \sigma^2)$$

- Uncertainty solely depends on estimated noise level σ^2
 - I.e. **noise is input independent**

Intermediate Wrap-up Bayesian Learning

- Treat **parameter vector as random variable** and estimate posterior
 - Estimate probability of “being right” for θ
- **Posterior** distribution is **integrated out for prediction**
 - All possible parameter vectors are used for the prediction
 - Weighted by probability of “being right”
- Posterior **quantifies our uncertainty in the model**
 - Can also be used to quantify uncertainty in the prediction

We will now look at 2 examples for Bayesian Learning:

- Bayesian Linear Regression
- Gaussian Processes

Today's Agenda!

Bayesian Learning:

- Posterior and Predictive Distribution
- Bayesian estimation for Gaussians
- Maximum A-posteriori (MAP) Estimates

Bayesian Regression Algorithms:

- Bayesian Linear Regression
- Gaussian Processes

Basics:

Gaussian Identities:

- Completing the Square
- Gaussian Bayes Rules
- Gaussian Propagation

Bayesian Linear Regression

For Bayesian Linear Regression, the **posterior and the prediction can be computed in closed form:**

- For all other cases, we need approximations
- While linear models are limited, it is still insightful to look at the properties of this case

Model:

- Likelihood (single sample): $p(y|\mathbf{x}, \mathbf{w}) = \mathcal{N}(y|\mathbf{w}^T \phi(\mathbf{x}), \sigma^2)$
 - Linear model
 - Noise variance
- Likelihood (full dataset): $p(\mathbf{y}|\mathbf{X}, \mathbf{w}) = \prod_i \mathcal{N}(y_i|\mathbf{w}^T \phi(\mathbf{x}_i), \sigma^2) = \underbrace{\mathcal{N}(\mathbf{y}|\Phi\mathbf{w}, \sigma^2 \mathbf{I})}_{\text{Multivariate distribution}}$
 - Feature Matrix
 - Multivariate distribution
 - Write product of independent Gaussians as multivariate Gaussian
- Gaussian prior: $p(\mathbf{w}) = \mathcal{N}(\mathbf{w}|\mathbf{0}, \lambda^{-1} \mathbf{I})$
 - Parameter precision

Bayesian Linear Regression

2 Steps:

1. Compute posterior

$$p(\mathbf{w}|\mathbf{X}, \mathbf{y}) = \frac{p(\mathbf{y}|\mathbf{X}, \mathbf{w})p(\mathbf{w})}{p(\mathbf{y}|\mathbf{X})} = \frac{\overset{\text{Likelihood}}{p(\mathbf{y}|\mathbf{X}, \mathbf{w})}\overset{\text{Prior}}{p(\mathbf{w})}}{\underset{\text{Evidence/Normalizer}}{\int p(\mathbf{y}|\mathbf{X}, \mathbf{w})p(\mathbf{w})d\mathbf{w}}}$$

2. Compute predictive distribution: Integrate posterior out

$$p(y^*|\mathbf{x}^*, \mathbf{X}, \mathbf{y}) = \int \overset{\text{Parameter-specific prediction}}{p(y^*|\mathbf{w}, \mathbf{x}^*)}\overset{\text{Posterior}}{p(\mathbf{w}|\mathbf{X}, \mathbf{y})}d\mathbf{w}$$

We have to look at some basics first...

Basics: Gaussian Identities

- Eq (1): **Joint** from **Marginal** and **Conditional**:

$$\mathcal{N}(\mathbf{x}|\boldsymbol{\mu}_x, \boldsymbol{\Sigma}_x)\mathcal{N}(\mathbf{y}|\mathbf{F}\mathbf{x}, \boldsymbol{\Sigma}_y) = \mathcal{N}\left(\begin{bmatrix} \mathbf{x} \\ \mathbf{y} \end{bmatrix} \mid \begin{bmatrix} \boldsymbol{\mu}_x \\ \mathbf{F}\boldsymbol{\mu}_x \end{bmatrix}, \begin{bmatrix} \boldsymbol{\Sigma}_x & \boldsymbol{\Sigma}_x\mathbf{F}^T \\ \mathbf{F}\boldsymbol{\Sigma}_x & \boldsymbol{\Sigma}_y + \mathbf{F}\boldsymbol{\Sigma}_x\mathbf{F}^T \end{bmatrix}\right)$$

- Eq (2): **Marginal** and **Conditional** Gaussian from **Joint**:

$$\mathcal{N}\left(\begin{bmatrix} \mathbf{x} \\ \mathbf{y} \end{bmatrix} \mid \begin{bmatrix} \boldsymbol{\mu}_x \\ \boldsymbol{\mu}_y \end{bmatrix}, \begin{bmatrix} \boldsymbol{\Sigma}_x & \mathbf{C} \\ \mathbf{C}^T & \boldsymbol{\Sigma}_y \end{bmatrix}\right) = \mathcal{N}(\mathbf{x}|\boldsymbol{\mu}_x, \boldsymbol{\Sigma}_x)\mathcal{N}(\mathbf{y}|\boldsymbol{\mu}_y + \mathbf{C}^T\boldsymbol{\Sigma}_x^{-1}(\mathbf{x} - \boldsymbol{\mu}_x), \boldsymbol{\Sigma}_y - \mathbf{C}^T\boldsymbol{\Sigma}_x^{-1}\mathbf{C}).$$

- Can also be derived by “completing the square”...

Basics: Gaussian Bayes rule

Bayes rule for Gaussian distribution:

- Marginal: $p(\mathbf{x}) = \mathcal{N}(\mathbf{x}|\boldsymbol{\mu}_x, \boldsymbol{\Sigma}_x)$
- Conditional: $p(\mathbf{y}|\mathbf{x}) = \mathcal{N}(\mathbf{y}|\mathbf{F}\mathbf{x}, \sigma_y^2\mathbf{I})$
- **Gaussian Bayes Rule 1:** The posterior $p(\mathbf{x}|\mathbf{y})$ is Gaussian with
 - Mean: $\boldsymbol{\mu}_{x|\mathbf{y}} = \boldsymbol{\mu}_x + \boldsymbol{\Sigma}_x\mathbf{F}^T(\sigma_y^2\mathbf{I} + \mathbf{F}\boldsymbol{\Sigma}_x\mathbf{F}^T)^{-1}(\mathbf{y} - \mathbf{F}\boldsymbol{\mu}_x)$
 - Covariance: $\boldsymbol{\Sigma}_{x|\mathbf{y}} = \boldsymbol{\Sigma}_x - \boldsymbol{\Sigma}_x\mathbf{F}^T(\sigma_y^2\mathbf{I} + \mathbf{F}\boldsymbol{\Sigma}_x\mathbf{F}^T)^{-1}\mathbf{F}\boldsymbol{\Sigma}_x$
- **Derivation:**
 - Use Eq (1) to form joint $p(\mathbf{x}, \mathbf{y})$ from marginal $p(\mathbf{x})$ and conditional $p(\mathbf{y}|\mathbf{x})$
 - Use Eq (2) to form posterior $p(\mathbf{x}|\mathbf{y})$ from joint $p(\mathbf{x}, \mathbf{y})$

Basics: Gaussian Bayes rule

Bayes rule for Gaussian distribution:

- Marginal: $p(\mathbf{x}) = \mathcal{N}(\mathbf{x}|\boldsymbol{\mu}_x, \boldsymbol{\Sigma}_x)$
- Conditional: $p(\mathbf{y}|\mathbf{x}) = \mathcal{N}(\mathbf{y}|\mathbf{F}\mathbf{x}, \sigma_y^2\mathbf{I})$
- **Gaussian Bayes Rule 2:** The posterior $p(\mathbf{x}|\mathbf{y})$ is Gaussian with
 - Mean: $\boldsymbol{\mu}_{x|\mathbf{y}} = \boldsymbol{\mu}_x + (\sigma_y^2\mathbf{I} + \boldsymbol{\Sigma}_x\mathbf{F}^T\mathbf{F})^{-1}\boldsymbol{\Sigma}_x\mathbf{F}^T(\mathbf{y} - \mathbf{F}\boldsymbol{\mu}_x)$
 - Covariance: $\boldsymbol{\Sigma}_{x|\mathbf{y}} = (\boldsymbol{\Sigma}_x^{-1} + \sigma_y^{-2}\mathbf{F}^T\mathbf{F})^{-1} = \sigma_y^2(\sigma_y^2\mathbf{I} + \boldsymbol{\Sigma}_x\mathbf{F}^T\mathbf{F})^{-1}\boldsymbol{\Sigma}_x$
- **Derivation: Use following identities for Bayes rule 1 from the matrix cookbook...**
 - Use identity $\mathbf{A}(\mathbf{I} + \mathbf{B}\mathbf{A})^{-1} = (\mathbf{I} + \mathbf{A}\mathbf{B})^{-1}\mathbf{A}$ for the mean (Searl identity)
 - Use identity $(\mathbf{A} + \mathbf{C}\mathbf{B}\mathbf{C}^T)^{-1} = \mathbf{A}^{-1} - \mathbf{A}^{-1}\mathbf{C}(\mathbf{B}^{-1} + \mathbf{C}^T\mathbf{A}^{-1}\mathbf{C})^{-1}\mathbf{C}^T\mathbf{A}^{-1}$ for the covariance (Woodbury identity)

Basics: Gaussian Bayes rule

- **Gaussian Bayes Rule 1**

- Mean: $\mu_{x|y} = \mu_x + \Sigma_x F^T (\sigma_y^2 I + F \Sigma_x F^T)^{-1} (y - F \mu_x)$
- Covariance: $\Sigma_{x|y} = \Sigma_x - \Sigma_x F^T (\sigma_y^2 I + F \Sigma_x F^T)^{-1} F \Sigma_x$

- **Gaussian Bayes Rule 2:**

- Mean: $\mu_{x|y} = \mu_x + (\sigma_y^2 \Sigma_x^{-1} + F^T F)^{-1} F^T (y - F \mu_x)$
- Covariance: $\Sigma_{x|y} = \sigma_y^2 (\sigma_y^2 \Sigma_x^{-1} + F^T F)^{-1}$

Observations: Both rules are mathematically equivalent...

- However, **numerically it can be a huge difference**
 - Bayes rule 1: Invert a matrix with dimension $dim(y) \times dim(y)$
 - Bayes rule 2: Invert a matrix with dimension $dim(x) \times dim(x)$
- Use Rule 1 if $dim(y) < dim(x)$, otherwise Rule 2

Basics: Gaussian propagation

Given marginal $p(\mathbf{x}) = \mathcal{N}(\mathbf{x}|\boldsymbol{\mu}_x, \boldsymbol{\Sigma}_x)$ and conditional $p(\mathbf{y}|\mathbf{x}) = \mathcal{N}(\mathbf{y}|\mathbf{F}\mathbf{x}, \sigma_y^2\mathbf{I})$ we want to obtain the marginal for \mathbf{y}

- The marginal distribution $p(\mathbf{y}) = \int p(\mathbf{x})p(\mathbf{y}|\mathbf{x})d\mathbf{x}$ is Gaussian with
 - Mean: $\boldsymbol{\mu}_y = \mathbf{F}\boldsymbol{\mu}_x$
 - Variance: $\boldsymbol{\Sigma}_y = \sigma_y^2\mathbf{I} + \mathbf{F}\boldsymbol{\Sigma}_x\mathbf{F}^T$
- Derivation:
 - Use Eq (1) to obtain joint distribution
 - Marginal $p(\mathbf{y})$ can be directly read from the joint
- Variance in \mathbf{y} increases due to uncertainty in \mathbf{x}

Ok... now we are ready to derive Bayesian Linear Regression!

Computing the Posterior

- Likelihood (conditional): $p(\mathbf{y}|\mathbf{X}, \mathbf{w}) = \mathcal{N}(\mathbf{y}|\Phi\mathbf{w}, \sigma^2\mathbf{I})$
- Prior (marginal): $p(\mathbf{w}) = \mathcal{N}(\mathbf{w}|\mathbf{0}, \lambda^{-1}\mathbf{I})$
- Dimensions: $\mathbf{w} \in \mathbb{R}^d$ and $\mathbf{Y} \in \mathbb{R}^{N \times 1}$, typically $d \ll N$

As the dimensionality of the marginal variable (parameter vector) is smaller than dimensionality of cond. variable (number of datapoints), we have to use **Gaussian Bayes rule 2!**

$$\boldsymbol{\mu}_{\mathbf{x}|\mathbf{y}} = \boldsymbol{\mu}_{\mathbf{x}} + (\sigma_{\mathbf{y}}^2 \boldsymbol{\Sigma}_{\mathbf{x}}^{-1} + \mathbf{F}^T \mathbf{F})^{-1} \mathbf{F}^T (\mathbf{y} - \mathbf{F} \boldsymbol{\mu}_{\mathbf{x}})$$

$$\boldsymbol{\Sigma}_{\mathbf{x}|\mathbf{y}} = \sigma_{\mathbf{y}}^2 (\sigma_{\mathbf{y}}^2 \boldsymbol{\Sigma}_{\mathbf{x}}^{-1} + \mathbf{F}^T \mathbf{F})^{-1}$$

- with $\boldsymbol{\mu}_{\mathbf{x}} = \mathbf{0}$, $\boldsymbol{\Sigma}_{\mathbf{x}} = \lambda^{-1}\mathbf{I}$, $\mathbf{F} = \Phi$ and $\sigma_{\mathbf{y}}^2 = \sigma_{\mathbf{y}}^2$

Computing the Posterior

Posterior $p(\mathbf{w}|\mathbf{X}, \mathbf{y}) = \mathcal{N}(\mathbf{w}|\boldsymbol{\mu}_{\mathbf{w}|\mathbf{X}, \mathbf{y}}, \boldsymbol{\Sigma}_{\mathbf{w}|\mathbf{X}, \mathbf{y}})$:

- Posterior mean: $\boldsymbol{\mu}_{\mathbf{w}|\mathbf{X}, \mathbf{y}} = (\boldsymbol{\Phi}^T \boldsymbol{\Phi} + \sigma_{\mathbf{y}}^2 \lambda \mathbf{I})^{-1} \boldsymbol{\Phi}^T \mathbf{y}$
- Posterior covariance: $\boldsymbol{\Sigma}_{\mathbf{w}|\mathbf{X}, \mathbf{y}} = \sigma_{\mathbf{y}}^2 (\boldsymbol{\Phi}^T \boldsymbol{\Phi} + \sigma_{\mathbf{y}}^2 \lambda \mathbf{I})^{-1}$

Observations:

- The **posterior mean is equivalent to the MAP** estimate
- ... results from the linearity of the likelihood (not the case for non-linear models)

So whats the advantage?

- We also get an **uncertainty estimate for the parameter vector!**

Example: Samples from the posterior

- We can create samples

$$\mathbf{w}_i \sim p(\mathbf{w} | \mathbf{X}, \mathbf{y})$$

- Each \mathbf{w}_i represents a function

$$f_i(\mathbf{x}) = \mathbf{w}_i^T \boldsymbol{\phi}(\mathbf{x})$$

- Basis functions are given by RBF basis functions

Predictive Distribution

The predictive distribution is given by:

$$\begin{aligned} p(y^* | \mathbf{x}^*, \mathbf{X}, \mathbf{y}) &= \int p(y^* | \mathbf{w}, \mathbf{x}^*) p(\mathbf{w} | \mathbf{X}, \mathbf{y}) d\mathbf{w} \\ &= \int \mathcal{N}(y_* | \phi_*^T \mathbf{w}, \sigma_y^2) \mathcal{N}(\mathbf{w} | \boldsymbol{\mu}_{\mathbf{w} | \mathbf{X}, \mathbf{y}}, \boldsymbol{\Sigma}_{\mathbf{w} | \mathbf{X}, \mathbf{y}}) d\mathbf{w} \end{aligned}$$

- Using **Gaussian propagation**, we can evaluate the predictive distribution. It is Gaussian with
 - Mean: $\mu(\mathbf{x}^*) = \phi(\mathbf{x}^*)^T (\boldsymbol{\Phi}^T \boldsymbol{\Phi} + \lambda \sigma_y^2 \mathbf{I})^{-1} \boldsymbol{\Phi}^T \mathbf{y}$
 - Variance: $\sigma^2(\mathbf{x}^*) = \sigma_y^2 \left(1 + \phi(\mathbf{x}^*)^T (\boldsymbol{\Phi}^T \boldsymbol{\Phi} + \lambda \sigma_y^2 \mathbf{I})^{-1} \phi(\mathbf{x}^*) \right)$
- Nothing new for the mean (same as Ridge Regression / MAP solution)
- **However:** The **variance is now input dependent!**

Example: Predictive Distribution

Visualize predictive distribution with

$$\mu(\mathbf{x}^*) \pm 2\sigma(\mathbf{x}^*)$$

- Model uncertainty is reduced if training data **contains information about weight for specific feature**
- In the limit $N \rightarrow \infty$ **model uncertainty vanishes** and only noise variance σ_y^2 remains

Today's Agenda!

Bayesian Learning:

- Posterior and Predictive Distribution
- Bayesian estimation for Gaussians
- Maximum A-posteriori (MAP) Estimates

Bayesian Regression Algorithms:

- Bayesian Linear Regression
- Gaussian Processes

Basics:

Gaussian Identities:

- Completing the Square
- Gaussian Bayes Rules
- Gaussian Propagation

Gaussian Processes

A Gaussian Process (GP) $f(\mathbf{x}) \sim \mathcal{GP}\left(\underbrace{m(\mathbf{x})}_{\text{mean function}}, \underbrace{k(\mathbf{x}, \mathbf{x}')}_{\text{covariance function}}\right)$

is a **probability distribution over functions** $f(\mathbf{x})$, such that any finite set of function values $t_i = f(\mathbf{x}_i)$ evaluated at inputs $\mathbf{x}_1, \dots, \mathbf{x}_n$ is **jointly Gaussian distributed**

- Mean function evaluates our **prior belief** about the function

$$\mathbb{E}[f(\mathbf{x})] = m(\mathbf{x})$$

- For simplicity, we will use $m(\mathbf{x}) = 0$

- Covariance function evaluates how **similar/correlated two function evaluations** at inputs \mathbf{x}, \mathbf{x}' are

$$\mathbb{E}[f(\mathbf{x})f(\mathbf{x}')] = k(\mathbf{x}, \mathbf{x}')$$

- Covariance function needs to be a **positive definite function** (similar to a kernel function)

Different covariance functions

Samples from a GP prior with different covariance functions

- The covariance encodes our **prior belief in the smoothness** of the function

$$k(\mathbf{x}_i, \mathbf{x}_j) = \exp\left(-\frac{1}{2\sigma^2} \|\mathbf{x}_i - \mathbf{x}_j\|^2\right)$$

Gaussian Kernel

$$k(\mathbf{x}_i, \mathbf{x}_j) = \exp(-\theta \|\mathbf{x}_i - \mathbf{x}_j\|)$$

**Ornstein-Uhlenbeck Process
(Brownian Motion)**

Gaussian Processes

I.e. a Gaussian process over N function evaluations $\mathbf{t} = [t_1, \dots, t_N]^T$ is completely **specified by the 2nd order statistics**, i.e., mean and covariance, i.e.

$$p(\mathbf{t}|\mathbf{X}) = \mathcal{N}(\mathbf{t}|\mathbf{0}, \mathbf{K}) \quad \text{with} \quad \mathbf{K} = \begin{bmatrix} k(\mathbf{x}_1, \mathbf{x}_1) & \dots & k(\mathbf{x}_1, \mathbf{x}_N) \\ \vdots & \ddots & \vdots \\ k(\mathbf{x}_N, \mathbf{x}_1) & \dots & k(\mathbf{x}_N, \mathbf{x}_N) \end{bmatrix}$$

In reality, we can only **measure noisy function** values, i.e. $y_i = f(\mathbf{x}_i) + \epsilon$, $\epsilon \sim \mathcal{N}(0, \sigma_y^2)$. We get the following Gaussian distribution over \mathbf{y}

$$\begin{aligned} p(\mathbf{y}|\mathbf{X}) &= \int p(\mathbf{y}|\mathbf{t})p(\mathbf{t}|\mathbf{X})d\mathbf{t} \\ &= \int \mathcal{N}(\mathbf{y}|\mathbf{t}, \sigma_y^2\mathbf{I})\mathcal{N}(\mathbf{t}|\mathbf{0}, \mathbf{K})d\mathbf{t} \dots \text{Gaussian propagation} \\ &= \mathcal{N}(\mathbf{y}|\mathbf{0}, \mathbf{K} + \sigma_y^2\mathbf{I}) \end{aligned}$$

Predictive distribution

We know that the function values \mathbf{y} for the training set \mathbf{X} and for a new data point \mathbf{x}^* are jointly Gaussian distributed. Hence, also the **conditional** $p(y^*|\mathbf{X}, \mathbf{y}, \mathbf{x}^*)$ **is also Gaussian distributed**.

- For a new data-point y^* we can obtain the joint distribution over function values

$$p\left(\begin{bmatrix} \mathbf{y} \\ y^* \end{bmatrix} \middle| \begin{bmatrix} \mathbf{X} \\ \mathbf{x}^* \end{bmatrix}\right) = \mathcal{N}\left(\begin{bmatrix} \mathbf{y} \\ y^* \end{bmatrix} \middle| \begin{bmatrix} \mathbf{K} + \sigma_y^2 \mathbf{I} & \mathbf{k}_{\mathbf{x}^*} \\ \mathbf{k}_{\mathbf{x}^*}^T & k^* + \sigma_y^2 \end{bmatrix}\right)$$

\mathbf{K} ... kernel matrix, $\mathbf{k}_{\mathbf{x}^*} = [k(\mathbf{x}_1, \mathbf{x}^*), \dots, k(\mathbf{x}_N, \mathbf{x}^*)]^T$... kernel vector, $k^* = k(\mathbf{x}^*, \mathbf{x}^*)$

- We can **condition on \mathbf{y}** to obtain $p(y^*|\mathbf{X}, \mathbf{y}, \mathbf{x}^*)$ using the Gaussian identities (Eq. 2). The predictive distribution is Gaussian with
 - Mean: $\mu(\mathbf{x}^*) = \mathbf{k}_{\mathbf{x}^*}^T (\mathbf{K} + \sigma_y^2 \mathbf{I})^{-1} \mathbf{y}$
 - Variance: $\sigma(\mathbf{x}^*) = k^* + \sigma_y - \mathbf{k}_{\mathbf{x}^*}^T (\mathbf{K} + \sigma_y^2 \mathbf{I})^{-1} \mathbf{k}_{\mathbf{x}^*}$

Predictive distribution

Predictive GP distribution:

- Mean:

$$\mu(\mathbf{x}^*) = \mathbf{k}_{\mathbf{x}^*}^T (\mathbf{K} + \sigma_y^2 \mathbf{I})^{-1} \mathbf{y}$$

- Variance:

$$\sigma^2(\mathbf{x}^*) = k^* + \sigma_y^2 - \mathbf{k}_{\mathbf{x}^*}^T (\mathbf{K} + \sigma_y^2 \mathbf{I})^{-1} \mathbf{k}_{\mathbf{x}^*}$$

Observations:

- The mean corresponds to the Kernel Ridge Regression solution
- Yet, we also get an input dependent variance estimate
- Variance is reduced if kernel activations are high

Example of Sinusoidal Data Set (green: true function; blue: noisy data; red: GPR predictive mean; shaded: $\pm 2\sigma$)

Illustration of Posterior

Samples of the **prior** and the **posterior** (after conditioning on y)

(a), prior

(b), posterior

Weight space view

So why are GPs an instance of Bayesian Learning?

- We can also **derive GPs** from the **Bayesian Linear Regression** view
- **Kernelized version** of Bayesian Linear Regression (with infinite dimensional feature spaces)

So back to Bayesian linear regression....

- Likelihood (conditional): $p(\mathbf{y}|\mathbf{X}, \mathbf{w}) = \mathcal{N}(\mathbf{y}|\Phi\mathbf{w}, \sigma_y^2\mathbf{I})$
- Prior (marginal): $p(\mathbf{w}) = \mathcal{N}(\mathbf{w}|\mathbf{0}, \lambda^{-1}\mathbf{I})$
- Dimensions: $\mathbf{w} \in \mathbb{R}^d$ and $\mathbf{Y} \in \mathbb{R}^{N \times 1}$, **high/infinite dimensional features** $d \gg N$

As the dimensionality of the marginal variable (parameter vector) **is now larger** than dimensionality of cond. Variable (number of samples), we have to use **Gaussian Bayes rule 1**

Recap: Gaussian Bayes rule

- **Gaussian Bayes Rule 1**

- Mean: $\mu_{x|y} = \mu_x + \Sigma_x F^T (\sigma_y^2 I + F \Sigma_x F^T)^{-1} (y - F \mu_x)$
- Covariance: $\Sigma_{x|y} = \Sigma_x - \Sigma_x F^T (\sigma_y^2 I + F \Sigma_x F^T)^{-1} F \Sigma_x$

- **Gaussian Bayes Rule 2:**

- Mean: $\mu_{x|y} = \mu_x + (\sigma_y^2 \Sigma_x^{-1} + F^T F)^{-1} F^T (y - F \mu_x)$
- Covariance: $\Sigma_{x|y} = \sigma_y^2 (\sigma_y^2 \Sigma_x^{-1} + F^T F)^{-1}$

Observations: Both rules are mathematically equivalent...

- However, **numerically it can be a huge difference**
 - Bayes rule 1: Invert a matrix with dimension $dim(y) \times dim(y)$
 - Bayes rule 2: Invert a matrix with dimension $dim(x) \times dim(x)$
- Use Rule 1 if $dim(y) < dim(x)$, otherwise Rule 2

Recap: A few kernel identities

A kernel is an inner product of a feature space: $k(\mathbf{x}, \mathbf{x}') = \langle \phi(\mathbf{x}), \phi(\mathbf{x}') \rangle = \phi(\mathbf{x})^T \phi(\mathbf{x}')$

Let $\Phi_X = \begin{bmatrix} \phi(\mathbf{x}_1)^T \\ \vdots \\ \phi(\mathbf{x}_N)^T \end{bmatrix} \in \mathbb{R}^{N \times d}$ then the following identities hold:

- **Kernel matrix:** $\mathbf{K} = \Phi_X \Phi_X^T$

- Check: $[\mathbf{K}]_{ij} = \phi(\mathbf{x}_i)^T \phi(\mathbf{x}_j) = k(\mathbf{x}_i, \mathbf{x}_j)$

- **Kernel vector:** $\mathbf{k}_{\mathbf{x}^*} = \begin{bmatrix} k(\mathbf{x}_1, \mathbf{x}^*) \\ \vdots \\ k(\mathbf{x}_N, \mathbf{x}^*) \end{bmatrix} = \begin{bmatrix} \phi(\mathbf{x}_1)^T \phi(\mathbf{x}^*) \\ \vdots \\ \phi(\mathbf{x}_N)^T \phi(\mathbf{x}^*) \end{bmatrix} = \Phi_X \phi(\mathbf{x}^*)$

Recap: A few kernel identities

A kernel is an inner product of a feature space: $k(\mathbf{x}, \mathbf{x}') = \lambda^{-1} \langle \phi(\mathbf{x}), \phi(\mathbf{x}') \rangle = \lambda^{-1} \phi(\mathbf{x})^T \phi(\mathbf{x}')$

Let $\Phi_X = \begin{bmatrix} \phi(\mathbf{x}_1)^T \\ \vdots \\ \phi(\mathbf{x}_N)^T \end{bmatrix} \in \mathbb{R}^{N \times d}$ then the following identities hold:

- **Kernel matrix:** $\mathbf{K} = \lambda^{-1} \Phi_X \Phi_X^T$

- Check: $[\mathbf{K}]_{ij} = \lambda^{-1} \phi(\mathbf{x}_i)^T \phi(\mathbf{x}_j) = k(\mathbf{x}_i, \mathbf{x}_j)$

- **Kernel vector:** $\mathbf{k}_{\mathbf{x}^*} = \begin{bmatrix} k(\mathbf{x}_1, \mathbf{x}^*) \\ \vdots \\ k(\mathbf{x}_N, \mathbf{x}^*) \end{bmatrix} = \lambda^{-1} \begin{bmatrix} \phi(\mathbf{x}_1)^T \phi(\mathbf{x}^*) \\ \vdots \\ \phi(\mathbf{x}_N)^T \phi(\mathbf{x}^*) \end{bmatrix} = \lambda^{-1} \Phi_X \phi(\mathbf{x}^*)$

In the Bayesian case, we will subsume the prior precision λ into the kernel

Computing the Posterior

Using the **Gaussian Bayes Rule 1** results in the following posterior:

$$\mu_{\mathbf{w}|\mathbf{X},\mathbf{y}} = \lambda^{-1}\Phi^T(\sigma_y^2\mathbf{I} + \underbrace{\lambda^{-1}\Phi\Phi^T}_{\mathbf{K}})^{-1}\mathbf{y}$$

$$\Sigma_{\mathbf{w}|\mathbf{X},\mathbf{y}} = \lambda^{-1}\mathbf{I} - \lambda^{-2}\Phi^T(\underbrace{\sigma_y^2\mathbf{I} + \mathbf{K}}_{N \times N \text{ matrix}})^{-1}\Phi$$

- We used the **Kernel trick** to evaluate the inverse matrix
 - The prior precision λ has been subsumed in the kernel
- Both quantities are still **potentially infinite dimensional** and can not be evaluated!

Predictive distribution

Still, we can use the posterior to **evaluate the predictive distribution** (again using the Kernel trick)

$$\begin{aligned} p(y^* | \mathbf{x}^*, \mathbf{X}, \mathbf{y}) &= \int p(y^* | \mathbf{w}, \mathbf{x}^*) p(\mathbf{w} | \mathbf{X}, \mathbf{y}) d\mathbf{w} \\ &= \int \mathcal{N}(y_* | \phi_*^T \mathbf{w}, \sigma_y^2) \mathcal{N}(\mathbf{w} | \boldsymbol{\mu}_{\mathbf{w} | \mathbf{X}, \mathbf{y}}, \boldsymbol{\Sigma}_{\mathbf{w} | \mathbf{X}, \mathbf{y}}) d\mathbf{w} \end{aligned}$$

The **predictive distribution is again Gaussian** with

- Mean:
$$\begin{aligned} \mu(\mathbf{x}^*) &= \lambda^{-1} \phi(\mathbf{x}^*)^T \boldsymbol{\Phi}^T (\sigma_y^2 \mathbf{I} + \mathbf{K})^{-1} \mathbf{y} \\ &= \mathbf{k}_{\mathbf{x}^*}^T (\sigma_y^2 \mathbf{I} + \mathbf{K})^{-1} \mathbf{y} \end{aligned}$$
- Variance:
$$\begin{aligned} \sigma(\mathbf{x}^*) &= \sigma_y^2 + \lambda^{-1} \phi(\mathbf{x}^*)^T \phi(\mathbf{x}^*) - \lambda^{-2} \phi(\mathbf{x}^*)^T \boldsymbol{\Phi}^T (\sigma_y^2 \mathbf{I} + \mathbf{K})^{-1} \boldsymbol{\Phi} \phi(\mathbf{x}^*) \\ &= \sigma_y^2 + k^* - \mathbf{k}_{\mathbf{x}^*}^T (\sigma_y^2 \mathbf{I} + \mathbf{K})^{-1} \mathbf{k}_{\mathbf{x}^*} \end{aligned}$$

Gerhard Neumann | Machine Learning 1 | KIT | WS 2021/2022 ... **which is the same result as obtained with Gaussian conditioning**

Wrap-up: GP derivations

Function View:

- A Gaussian process is a distribution over functions, where every set of N function evaluations is jointly Gaussian distributed
- Predictions can hence be performed by conditioning

Weight Space View:

- A Gaussian process is a **Bayesian Kernel Regression** approach
- Underlying feature space is **potentially infinite dimensional**
- **Weight vector** (which is not representable) is integrated out using the Kernel trick

While GP for Regression is computationally very expensive ($O(N^3)$), it is one of the most principled approaches to statistical learning for regression

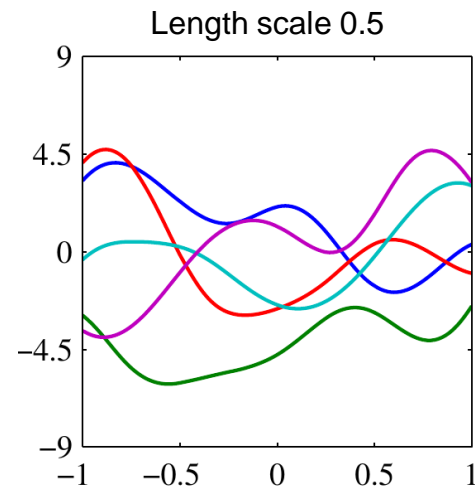

Kernels and Hyperparameters

- The parameters of the kernel (e.g. length-scale of Gaussian kernel) are called “**hyper-parameters**” β .
- The prior precision of the weights as well as the observation noise are for simplicity also subsumed in the kernel hyper-parameters

The most common kernel is the **Gaussian / RBF / squared-exponential Kernel**

$$k(\mathbf{x}_i, \mathbf{x}_j) = \lambda^{-1} \exp\left(-\frac{\|\mathbf{x}_i - \mathbf{x}_j\|}{2l^2}\right) + \delta_{ij}\sigma_y^2$$

- $\lambda \dots$ prior precision of the weight vector
- $\sigma_y^2 \dots$ noise variance
 - (only applied if $i = j$, in this notation $\mathbf{K} + \sigma_y^2 \mathbf{I}$ is replaced by \mathbf{C})
- $l \dots$ length scale

Influence of the Hyper-Parameters

Different noise levels

Too big / Underfitting

About right

Too small / Overfitting

Different length scales

Too big / Underfitting

About right

Too small / Overfitting

Kernels and Hyperparameters

Squared-exponential Kernel can be extended with a **length-scale per dimension**

$$k(\mathbf{x}_i, \mathbf{x}_j) = \lambda^{-1} \exp \left(- \sum_{k=1}^d \frac{(x_{i,k} - x_{j,k})^2}{2l_k^2} \right) + \delta_{ij} \sigma_y^2$$

- $\lambda \dots$ prior precision of the weight vector
- $\sigma^2 \dots$ noise variance (only applied if $i = j$)
- $l_k \dots$ length scale for dimension k

Also called Automatic Relevance Determination (ARD) kernel:

- Optimizing the length-scale determines the relevance of each dimension
- Large length-scale \rightarrow dimension is less important

Optimization of the Hyperparameters

- In GPs, the parameters \mathbf{w} can be integrated out in closed form
- Yet, no closed form solution exists for the hyper-parameters

Objective: Log-likelihood of the training data

$$\begin{aligned}\beta^* &= \arg \max_{\beta} \log \mathcal{N}(\mathbf{y}|\mathbf{0}, \mathbf{C}_{\beta}) \\ &= \arg \max_{\beta} -\frac{1}{2} \log |\mathbf{C}_{\beta}| - \frac{1}{2} \mathbf{y}^T \mathbf{C}_{\beta}^{-1} \mathbf{y} - \frac{N}{2} \log(2\pi)\end{aligned}$$

- Need to be optimized via gradient descent (only batch)
- **Non-convex**, multiple optima
- Only a **small number** of hyper-parameters
- Very flexible representation, **beware of overfitting** (would be better to do that on validation set)!

Example: Gene Expression

- Given gene expression levels in the form of a time series
- Want to detect if a gene is expressed or not, fit a GP to each gene [Kalaitzis and Lawrence, 2011]

A Simple Approach to Ranking Differentially Expressed Gene Expression Time Courses through Gaussian Process Regression

Alfredo A Kalaitzis* and Neil D Lawrence*

Abstract

Background: The analysis of gene expression from time series underpins many biological studies. Two basic forms of analysis recur for data of this type: removing inactive (quiet) genes from the study and determining which genes are differentially expressed. Often these analysis stages are applied disregarding the fact that the data is drawn from a time series. In this paper we propose a simple model for accounting for the underlying temporal nature of the data based on a Gaussian process.

Results: We review Gaussian process (GP) regression for estimating the continuous trajectories underlying in gene expression time series. We present a simple approach which can be used to filter quiet genes, or for the case of time series in the form of expression ratios, quantify differential expression. We assess via ROC curves the rankings produced by our regression framework and compare them to a recently proposed hierarchical Bayesian model for

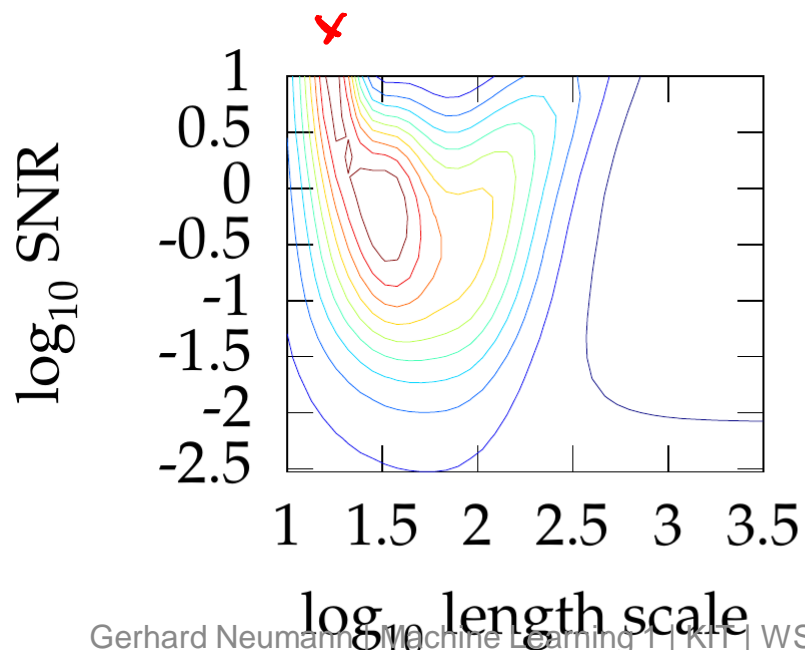

Example: GP Log-Likelihood

- Contour plot of the log-likelihood
- We can see multiple optima in the plot
- SNR = signal to noise ratio (ratio between lambda and sigma)

Example: Multiple Optima

- Optimum 1: length scale of 1.2221 and log10 SNR of 1.9654
- Log-likelihood is -0.22317.

Example: Multiple Optima

- Optimum 2: length scale of 1.5162 and log10 SNR of 0.21306
- Log-likelihood is -0.23604.

Example: Multiple Optima

- Optimum 3: length scale of 2.9886 and log10 SNR of -4.506
- Log-likelihood is -2.1056.

GPs: Summary

- GPs are a **non-parametric Bayesian approach** to regression with possibly infinite feature spaces
- Can estimate **predictive uncertainty** by integrating out model uncertainty
- Resulting prediction equations are “straightforward” and **obtained in closed-form because of the Gaussian properties**
- Hyperparameter optimization more complex, non-convex and expensive
- While GP for Regression is computationally very expensive, it is one of the most principled approaches to statistical learning for regression
- For **small data-sets**, they typically also **outperform Neural Nets** by a large margin

Take-away messages

- **Bayesian learning consists of 2 steps:**
 - Compute posterior over parameters / models
 - Average over all parameters / models weighted by posterior
- **Both steps are in general intractable**
 - Can only be done for linear feature / kernelized regression models in closed form
 - For all other cases, we need to **rely on approximations**
- **However, theoretically one of the most powerful learning methods**
 - Robust against overfitting (averages over unspecified behaviour in between datapoints)
 - Does not require test set
 - Quantifies model uncertainty
 - **Hot research topic:** Bayesian Neural Network

Self-test questions

- What are the 2 basic steps behind Bayesian Learning?
- Why is Bayesian Learning more robust against overfitting?
- What happens with the posterior if we add more data to the training set?
- What is completing the square and how does it work?
- For which 2 cases can Bayesian Learning be solved in closed form?
- Which approximations can we use if no closed form is available?
- How can we derive Bayesian Linear regression
- What is the advantage of Bayesian Linear regression to Ridge regression? What is the conceptual difference?
- What is the major advantage of GPs over Kernel Ridge Regression?
- Why are GPs a Bayesian approach?
- What principle allowed deriving GPs from a Bayesian regression point of view?
